Abstract: [Authors' English summary modified] Authors discuss the reticulo-endotheliomas, their etiology and pathogenesis, and note similarity between the Hand-Schüller-Christian and Abt-Letterer-Siwe diseases. Acidophilic granuloma, the mild form of this disease seldom observed in general form are resistant to treatment and give poorer prognosis. They describe two observed cases. **Influence of Titanium and Molybdenum on the Magnetic Properties of Fe-Mn-Al Alloys.** Feszczenco-Czopiwski and I. Kozłowski. (International Foundry Congress, Warsaw, Sept., 1938; Foundry Trade Journal, 1938, vol. 59, Oct. 27, pp. 305-308). After discussing the work of W. Küster and of Bradley and Taylor on the ternary iron-nickel-aluminium system, the authors describe their own investigation of the magnetic properties of these alloys with additions of molybdenum and titanium. From data obtained from tests on more than 200 sand-cast specimens, they found that in most cases the coercive force and the remanence increased with decreased area of cross-section of the specimen. They found that the most effective heat treatment for producing the maximum

Detection of laminations in [steel boiler] plates by the ultrasonic method. L. Kozłowski and M. Kurek (Prace Badaw. Gidron. Inst. Met. Odlew., 1949, 1, 99-103; Metal Abstr., 1951, 19, 316).—The detection of laminations in a non-ageing boiler plate (C 0.12, Si 0.19, Mn 0.46, and Al 0.07%) by means of a Hughes supersonic flaw detector is described. The presence of a lamination is shown by a marked reduction of amplitude of the cathode-ray oscillogram. Results are confirmed by the subsequent deep etching of the sectioned plate.

Properties of Metals

\*Magnetic Permeability and Coercive Magnetic Field Strength Measurements of Samples of Magnetically Soft Materials. L. Kozłowski (Prace Inst. Met. Odlew., 1952, 4, (6), 397-404).—[In Polish]. The magnetic permeability and the coercive magnetic field strength of magnetically soft materials were measured by the ring-specimen and yokeless methods. The results obtained by these two methods agree closely, but the values obtained with the Koepsel permeameter for specimens of the same shape as those used in the yokeless method are almost twice as high. It is suggested that the Koepsel permeameter method (hitherto used as a standard test for straight bar specimens) should be replaced by the yokeless method described.—S. K. L.

Metallurgy

Pomiary przenikalnosci magnetycznej i napiecia koercyjnego sztabkowych prob materialow magnetycznych miedkich (Prace Inst. Metalurgii No. 6), Katowice, 1953, PWT, 6.5 ppl 8 figs., 5 tabs.

The author gives a review of the technical literature concerning the methods of measuring the magnetic permeability and the coercive intensity in straight bar specimens. Comparative measurements by the ring specimen and yokeless method were carried out, and the most suitable method of measurement tested. The results obtained when using the usual method of measuring the coercive intensity were compared with the results obtained with the same specimen with Koepcel permeameter. It was found that the values of the coercive intensity obtained by means of the yoke less method were very close to those obtained with the ring specimen method. The method described can be used as a basis for working out a standard of measuring the coercive intensity in straight bar specimens of magnetically soft materials.

Kozlowski L., Pogorecki K., Zak H. Method of Producing Alni, Alnico  
and Magnico Type Permanent Magnets.

Metoda produkcji odlewanych magnesów trwałych typu Alni,  
Alnico i Magnico. "Przemysł Mechaniczny" N° 5, 1924, pp. 156-159.  
7 figs, 3 tabs.

POL

The authors have evolved a method for the production of permanent magnets the composition of which includes, in addition to iron, such elements as carbon, nickel, copper, cobalt and aluminum. The method of forming, melting and casting such magnets is identical with that for all kinds of alloys irrespective of chemical composition. Heat treatment methods are, however, closely dependent on the chemical composition of the alloy and are decisive in obtaining the requisite magnetic properties. Single heat treatment consisting in the cooling of the casting — at a rate strictly adapted to the individual alloys — is resorted to in the case of Alni and Alnico alloys, or alternatively a method of double heat treatment consisting in the rapid cooling down from the saturation temperature and subsequent aging for several hours. Magnico type magnets are cooled down, in a magnetic field of a magnetizing force of the order of 1000 Oersteds, from roughly 1300°C to a temperature of 550°C, the rate of cooling being strictly adapted to the cross-section of the magnet, but not exceeding 5°C per second.

Title : Effect of Cathodic Hydrogen on the Magnetic Properties of Certain Ferromagnets.

Orig Pub : Arch. hutn., 1957, 2, No 3, 223-241

Abstract : An investigation was made of the influence of cathodic hydrogen on the magnetic properties of specimens made of low-carbon silicon steel, nickel, and permalloy. All measurements were in an open magnetic loop. The electrolyte employed was 1 n-H<sub>2</sub>SO<sub>4</sub> with addition of 0.2 grams of As<sub>2</sub>O<sub>3</sub>, with presumably 0.03 gram of selenium or tellurium per one liter of solution. Before hydrogenation, all specimens were subjected to annealing in vacuum at a temperature of 950 C for two hours. The increase in H<sub>c</sub> is rapid at the very start of the hydrogenation, but after ten to twenty minutes this increase is reduced, and after sixty minutes the changes become already very insignificant. Analogous changes in H<sub>c</sub> can be

observed during cathodic polarization in a solution of 1 n-H<sub>2</sub>SO<sub>4</sub> with addition of 30 mg of tellurium or selenium per one liter of solution. A particularly large increase in H<sub>c</sub> (> 100%) occurs in cathodic polarization of ribbons made of silicon steel (3.2% Si) for the thickness of 0.15 and 0.35 mm. In specimens of this kind a regeneration of approximately 20% of the magnitude of H<sub>c</sub> was established, a regeneration that takes place within several days. In exactly the same manner, the specimens made of 1 mm nickel sheet were subjected to cathodic polarization and an increase of more than 60% in H<sub>c</sub> was observed thereby. This change appears to be reversible, so that after several days the H<sub>c</sub> of hydrogenated specimens returns to the initial value and the process itself can be repeated and the results obtained are identical within the limits of accuracy. The formulas of modern theories of coercive stress of magnetically soft materials have been analyzed, as were the possibilities of their application to physical-chemical interpretation of the results obtained.

Title : The Effect of Cathodic Hydrogen on the Magnetic Properties of Chrome Nickel Austenitic Steel

Orig Pub : Bull. Acad. polon. sci., 1957, Cl. 3, 5, No 5, 519-522

Abstract : The article considers the variation of the magnetic saturation of austenitic steel as a function of the time of cathodic polarization. It next considers the process of restoration of magnetic properties in time and also of determination of the thickness of the surface layer encompassed in the variation of magnetic saturation. The results obtained confirm the conclusions by Eisenkolb and Ehrlich that the cathodic hydrogen occurs in austenitic steel very fast only up to a thin surface layer, of thickness on the order of several microns.

Kozłowski

Effect of addition of metal oxides on the structure and magnetic properties of barium ferrites? L. Kozłowski and Z. Zieliński. *Prace Inst. Hutańca*, 10, 305-312 (1958). The addn. of  $\text{Al}_2\text{O}_3$ ,  $\text{Bi}_2\text{O}_3$ ,  $\text{Mn}_2\text{O}_3$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{CoO}$ , and  $\text{NiO}$  to  $\text{Ba}_0.6\text{Fe}_2\text{O}_4$  is investigated in expts. where  $\text{Fe}^{+++}$  is replaced by the respective ions at a ratio of atoms ( $\text{Fe}^{+++}$  initial)/ $(\text{I})$  of 12 for the trivalent and of 0.2-11.93 for the bivalent atoms. The test specimens are prep'd. by wet grinding of a mixt. of  $\alpha\text{-Fe}_2\text{O}_3$  ( $<10 \mu$  particle size) contg. 99.8  $\text{Fe}_2\text{O}_3$ , 0.01 Mn, 0.035 Ni, 0.02% Ca, and traces of Mg, with calcined  $\text{BaCO}_3$  ( $<60 \mu$ ) contg. 77.4 BaO, 0.07 Ca, 0.8 Sr, and 0.0% Na and a 3rd component, e.g. Al, Bi, or Cr oxide,  $\text{MnCO}_3$ ,  $\text{NiCO}_3$ , or  $\text{Co}(\text{C}_4\text{H}_9\text{O}_4)_2 \cdot 4\text{H}_2\text{O}$ , of high purity (dry grinding for  $\text{NiCO}_3$ ). Cylinders of 50 mm. diam. are then formed at 500 kg./sq. cm.. The cylinders are sintered at 1100° for 4 hrs. to give the ferrites, which are then crushed and ground during 24 hrs., passed through a sieve of 10,000 mesh/sq. cm. and the powder formed under 5 tons/sq. cm. pressure into  $10 \times 10 \times 20$  mm. hexahedrons, sintered at 900°, 1000°, 1100°, 1150°, 1200°, 1300°, keeping the specimen for 2 hrs. at the final temp., and cooled. The specific induction of satn. ( $4\pi I_s$ ), magnetic remanence ( $4\pi I_r$ ), coercive force ( $H_c$ ), satn. magnetisation of unit mass ( $\sigma_s$ ), the phase analysis of the nonoriented and oriented ferrites in a magnetic field of 14,000 oe., the thermomagnetic curves, and their Curie temp. are then detd. Ferrites contg. oxides of Al, Mn, and Cr form continuous solid solns. in the lattice of I. Increased  $\text{Al}_2\text{O}_3$  content inhibits the growth of the ferrite crystals (1-42% mole %  $\text{Al}_2\text{O}_3$ , sp. gr. of the ferrite 6.2-4.8 g./cc.). At less than 15%  $\text{Al}_2\text{O}_3$  the dimensions of the elementary cell are considerably decreased; >15% the changes are much smaller. In the 1st stage the  $I_s$  and  $I_r$  decrease approx. linearly and the co-

ercive force increases, attaining a max. of 8000 oe. at 14 mole %  $\text{Al}_2\text{O}_3$ ; the ferrite being sintered at 1200-1300°. Addn. of Mn has causes practically a single phase sinter, and does not affect a change of the magnetocryst. anisotropy.  $I_s$  and  $I_r$  decrease almost linearly (greatest decrease at 1200 and 1300°), coercive force increases (max. at 1000-1100° sintered for 2 hrs.). Optimum magnetic properties are possessed by a ferrite contg. 10 mole %  $\text{Mn}_2\text{O}_3$  ( $I_s$ , 2000 gausses,  $I_r$ , 1400 and  $H_c$  4100 oe.) or at 1000-1100° sintered for 15 min. ( $I_s$ , 1300 and  $H_c$  4150 oe.). At 10%  $\text{Cr}_2\text{O}_3$  crystals of a new unidentified phase appear. All magnetic properties decrease on increasing the  $\text{Cr}_2\text{O}_3$  content.  $\text{Bi}_2\text{O}_3$ -contg. ferrites are well sintered at 1000°, have a sp. gr. of 6.2-6.9 g./cc. and improved melting qualities, and crystal growth is inhibited. At 2 mole %  $\text{Bi}_2\text{O}_3$  there appears a new nonmagnetic phase of unidentified structure and a solid soln. in the I lattice that proves that microovergrowths are formed in hexagonal layers. Addn. of less than 2%  $\text{Bi}_2\text{O}_3$  increases  $I_s$  and  $I_r$  by about 10%, and  $H_c$  by approx. 25%. Elementary cell changes are greater at 2-5% and practically nil at 5-10%, which is reflected in the small difference (30°) of the Curie temp. for 1% and 10% content. At less than 8%  $\text{CoO}$  or  $\text{NiO}$  a solid soln. is formed in the lattice of type I, magnetic properties of the sinters are worse than that of pure I, but the sinters still possess properties of hard magnetic material. Above 8%, a new magnetic phase, probably a soft magnetic phase, appears, which is isomorphous at 20%  $\text{NiO}$  or  $\text{CoO}$ .  $I_s$  and the coercive force, especially in ferrites sintered at higher temp., considerably decrease and the sinters have properties of a soft magnetic material. This phenomenon is very distinctive.

L. Kozlowski and Z. Ziolkowski

if NiO is added. At 10% NiO or CoO the I-type ferrite still exists and disappears at 40% at which compn. new compds. are formed. The sinters of NiO and CoO do not fit as hard magnets. The literature on the effect of a series of metal oxides on magnetic properties of Ba, Sr, and Pb ferrites is reviewed.

Kozłowski L., Zieliński Z. The Effect of Adding  $\text{Al}_2\text{O}_3$ ,  $\text{Mn}_2\text{O}_3$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{Bi}_2\text{O}_3$ ,  $\text{CaO}$  and  $\text{NiO}$  on the Structure and Magnetic Properties of Barium Ferrite.

"Wpływ dodatków  $\text{Al}_2\text{O}_3$ ,  $\text{Mn}_2\text{O}_3$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{Bi}_2\text{O}_3$ ,  $\text{CaO}$  i  $\text{NiO}$  na strukturę oraz właściwości magnetyczne ferrytów barowych". Przegląd Telekomunikacyjny, No. 1, 1959, pp. 5-10, 10 figs.

X-ray examinations and magnetic tests carried out with a view to determining the effect of adding  $\text{Al}_2\text{O}_3$ ,  $\text{Mn}_2\text{O}_3$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{Bi}_2\text{O}_3$ ,  $\text{CaO}$  and  $\text{NiO}$  on the structure and magnetic properties of barium ferrites used in the production of permanent magnets, show that adding  $\text{Al}_2\text{O}_3$ ,  $\text{Mn}_2\text{O}_3$  and  $\text{Bi}_2\text{O}_3$  to barium-aluminium, barium-manganese and barium-bismuth ferrites diminishes the speed of grain growth in sintered material, and that the sintering temperatures ensuring a low rate of growth are dependent upon the oxide being added. In order to ensure a uniform structure of barium-aluminium ferrite, sintering temperatures in excess of  $1200^\circ\text{C}$ . should be used. The effect of  $\text{Mn}_2\text{O}_3$  on the growth of grain is insignificant so that sintering temperatures should be between  $1000$  and  $1100^\circ\text{C}$ . At low  $\text{Bi}_2\text{O}_3$  content, the presence of an easily fusible stage facilitates sintering of the pressing at a relatively low temperature, a process which prevents the growth of grain and the drop of coercive force. Adding more than 2-5% of  $\text{Bi}_2\text{O}_3$  results in the formation of a new stage of an indefinable structure which counteracts the growth of grain at the stage  $\text{BaFe}_{12}\text{O}_{19}$ . Adding  $\text{Cr}_2$ ,  $\text{CaO}$  and  $\text{NiO}$  seriously affects the magnetic properties of barium ferrite.

The Relationship Between the Curves of Isothermal Austenite Transformation During Continuous Cooling. M. Kozai and H. Saito. (Transl.) [1964, IR, (3), 69-78]. (See below). The knowledge of the dependence of the initial and end temperatures of transformation of supercooled austenite on the cooling velocity provides a means of controlling the effect of hardening, i.e., the change in the mechanical and physical properties of the hardened object. The determination and application of curves of the initial transformation of supercooled austenite during continuous cooling are discussed. — T. G.

TITLE: Basic chromite-magnesite mass for refractory linings to induction furnaces

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 22, 1962, 355, abstract 22K252 (Pol. pat. 44922, September 21, 1961)

TEXT: The patent covers a refractory mass for lining steelmaking induction furnaces. The starting materials are chromite-magnesite tailings, calcined magnesite and a small amount of fluorite. A specific feature of the mass is its granulometric composition: chromite-magnesite tailings: 9-13 % with grain size 0.6-0.84 mm, 22-26 % with 0.84-1.68 mm, 18-22 % with 1.68-3.36 mm, 6-12 % with 3.36-6.72 mm and 8-12 % with 6.72-13.2 mm; magnesite: 28-32 % with grain size 0-0.20 mm and 3.5-5.5 % with 0.20-0.60 mm; fluorite 0.5 % with grain size 0-0.20 mm, all in wt.% related to the finished dry mixture. The authors observe that, used as a lining, this mass will increase the life of a furnace 4 times. [Abstracter's note: Complete translation.] ✓

TITLE: The diamagnetism of the Van Allen Zones as a possible source  
of the earth's external magnetic field

PERIODICAL: Acta Geophysica Polonica, v. 8, no. 4, 1960, 287 - 311

TEXT: The author attempts to find approximate expressions for the potential and the intensity of the magnetic field surrounding the earth's surface. Values are derived from measurements of the Van Allen Zones on the assumption of the diamagnetic behavior of their gases. The zones, according to Van Allen, are single layers, magnetized along the lines of force of the geomagnetic field. The magnetic properties of the Van Allen Zones influence the earth's magnetic field and play a significant part in the development of magnetic storms. Data were obtained from measurements made with the artificial satellites Pioneer III, Sputnik III and Pioneer IV. Van Allen radiation at its strongest occurs at an altitude of 3,000 km above the geomagnetic equator (inner Zone) and at a distance of approximately 30,000 km from the earth's center (outer Zone). The author quotes Van

The diamagnetism of the Van Allen Zones as...

Allen: "The trapped radiation acts as an intermediate reservoir of charged particles between the sun as source, and the earth's atmosphere. Resulting geophysical phenomena include the aurora, airglow, possible atmospheric heating, geomagnetic storms etc. In addition, the trapped radiation may be the seat of the electrical current long supposed to be responsible for the main phase of magnetic storms." In investigating the contribution of diamagnetism, the sole objective of this paper, the existence of density magnetisation is given by the equation:

$$\bar{\mu} = - \frac{N W_1 B}{B^2}$$

where  $W_1$  - the kinetic energy of particles in motion perpendicular to the lines of force;  $N$  - denotes density of particles;  $B$  - denotes the magnetic field. The author arrives at the final equation:

$$N_0^e \approx 1.4 \cdot 10^3 / \text{cm}^3$$

The value of  $N_0^e$  corresponds to the upper density limit. Density values for

TITLE: On the external magnetic field of the earth

SOURCE: Acta geophysica polonica, v. 12, no. 4, 1964, 209-250

TOPIC TAGS: earth's magnetic field, Van Allen belt, magnetic storm, ring current, disturbance, ring current

ABSTRACT: On the basis of the DR model of the magnetic storm (S. I. Akasofu and S. Chapman, Phil. Trans. Roy. Soc., London, Series A, v. 253, 359-406, 1961) and others), the author investigates the conditions of a self-consistent outer geomagnetic field when the force lines in this field are curved and the pressure is anisotropic. The critical ratio of the energy of the particle motion to the energy density of the magnetic field is determined by investigating the behavior of the current algebra invariant of the particles under conditions when the magnetic field has macroturbulence. The purpose of the investigation was to establish the degree to which these inhomogeneities can contribute to non-stationary course of the ring currents and of the DR field. The direction of the

Card: 1/3

L-23799-65

ACCESSION NR: AP5001623

ring current is investigated in the two-dimensional model of the principal phase of the magnetic storm. An attempt at confirming the existence of an external field as being due to an eastward ring current did not yield any results (in the Al'fven-Chapman model the ring current can have only a western direction). The critical energy, magnetic prefactor, and critical value of the pitch angle is calculated using the Al'fven approximation. It is found as a result that the magnetic moments of the protons, with energy of motion (perpendicular to the force lines) exceeding 17 kev, are perturbed. The lifetime of such protons in the ring-current zone is approximately 10 days, in good agreement with the duration of the magnetic storm. The period of one revolution of such protons around the earth is also in agreement with the growth time of the principal phase. The change in the magnetic moment of the protons moving in periodic orbits in the ring-current zone, in which the perturbations with small amplitudes arise simultaneously, is also calculated. Such waves disturb the adiabatic invariance of the particles, but the kinetic energy of the ring current remains practically unchanged. In spite of this, waves with amplitude comparable to the magnetic field intensity in the ring-current zone can give rise to magnetic scattering of protons. It is possible to deduce such a conclusion from the established correspondence between the intervals of the microvariations and the intervals of the faster

"The Influence of Fodder Oxytetracycline on Growth of Piglets Retarded in Their Development (Cachexia)"

Lublin, Medycyna Weterynaryjna, Vol 22, No 10, Oct 66; p. 616-618

Abstract [English summary modified]: Oxytetracycline 200 gm added to 1000 kg feed concentrate increased growth of underdeveloped piglets (below 12 kg at 8 weeks of age). Feed utilization was also improved. It did not decrease mortality, presumably due to advanced cachexia in some of the piglets. Table, graph, 1 Polish, 5 Western references.
